Received 3 January 1992

We examine some results and techniques of analytic number theory which have application, or potential application, in mathematical physics. We consider inversion formulae for lattice sums, various transformations of infinite series and products, functional equations and scaling relations, with selected applications in electrostatics and statistical mechanics. In the analysis, the Mellin transform and the Riemann zeta function play a key role.

1. Introduction

This paper was stimulated by a brief note of Chen [1], which attracted some interest. Chen showed how to effect the asymptotic solution of several standard inverse problems in statistical physics by invoking the Möbius inversion formula, an apparently obscure result of algebraic number theory. The cornerstone of Chen's analysis is equivalent to the assertion that, under modest hypotheses on the functions α and β , if

$$\alpha(x) = \sum_{n=1}^{\infty} \beta(nx) \quad \text{for all } x > 0, \quad (1.1)$$

¹ E-mail: hughes@mundoc.maths.mu.oz.au

then

$$\beta(x) = \sum_{n=1}^{\infty} \mu(n) \alpha(nx) \quad \text{for all } x > 0, \quad (1.2)$$

where the Möbius function $\mu(n)$ is defined by

$$\mu(n) = \begin{cases} 1, & n = 1, \\ (-1)^r, & \text{if } n \text{ has } r \text{ distinct prime factors,} \\ 0, & \text{otherwise.} \end{cases} \quad (1.3)$$

To number theorists this key result in Chen is utterly trivial and well known, and Chen [2] subsequently noted that the rather circuitous original derivation of eq. (2) can be replaced by appeal to theorem 270 in ref. [3], yet to physicists not familiar with analysis buried in the classics like Titchmarsh [4] or Hardy and Wright [3] some new magical tools seemed to have been invented. Indeed the Editor of Nature suggested [5] that by so calling in the treasure-trove of the old world some new insights into physics might become accessible.

In fact the resurgence of interest in classical analysis and in number theoretic formulae is of fairly long standing [6–8]. It is represented by the work of Andrews and of Askey on q -series and generalised hypergeometric functions [9], in Rogers–Ramanujan relations [10], in the popularity of Ramanujan's notebooks, which have finally become available [11], in work of Glasser and Zucker [12] on applications of number theory to the calculation of lattice sums, in a re-evaluation of R.B. Dingle's contribution to asymptotics [13], in Coxeter's astonishing results on sphere packing (discussed by Dyson [14]), in random walks with infinite variance [15], conferences on analytic number theory in physics, and the very beautiful work of the School associated with Dingle's student Berry at Bristol [16–19].

A paper of Dyson [14] is a classic and deep exposition of the kind of tantalising insights that might be coming into sight. To the average or garden variety physicist or chemist unfamiliar with what Dyson in his paper calls “unfashionable pursuits”, these matters are a deep mystery. The language of mathematicians is almost deliberately obscure in its pursuit of exactness, and designed to admit only the anointed to its hallowed halls of revealed truth. In fact all mathematics is a tautology, and all physics uses mathematics to look in different ways at a fundamental problem of philosophy – how to bridge the discrete and continuous. Much of the work discussed that skirts around the role of number theory in physics pays lip service to motivation through calling in physical problems, e.g. Brownian motion, distribution of eigenvalues of random matrices, whatever, but really represents mathematicians in search of an application. Although an exception can be found in the work of Berry, this

paper makes no significant inclusions into additive number theory.
 "The Riemann zeta function is central at least to multiplicative number theory. The present Mathematics is the Queen of the Sciences and Arithmetic is the Queen of Mathematics".

$$\int_0^x f(s) = \int_{-\infty}^x f(x) dx \quad (1.5)$$

Our discussion makes frequent use of the Mellin transform. Although this transform continually finds new and elegant applications [22, 23], it is not often useful in the solution of differential equations problems and is therefore summarized in the appendix of the paper.

The Mellin transform $\int(s)$ of a function $f(x)$ is defined by the integral $\int_0^\infty x^{s-1} f(x) dx$. Some results from the theory of theta functions are discussed in some series related to the electrostatic properties of crystalline and quasicrystalline solids. We conclude in section 8 with a product representation of the theta functions. The theory of new infinite equations, the theory of Euler's product and the derivation of new infinite series, with applications to the solution of nonlinear difference equations by Bellman [21], which the author is urged to consult. Section 4 contains an excursion into statistical mechanical systems with a maximum permissible temperature. Sections 5, 6 and 7 address the transform. Section 4 contains an excursion into statistical mechanical systems with a maximum permissible temperature. Sections 5, 6 and 7 address the transform. The point of view of infinite series, with applications to the solution of nonlinear difference equations by Bellman [21], which the author is urged to consult.

The point of view of infinite series, with applications to the solution of nonlinear difference equations by Bellman [21], which the author is urged to consult.

In section 2, we revisit the inversion formulae (1.1) and (1.2). Viewed from an appropiate perspective, these formulae and Chen's applications of them are about all there is to ponder. But the proposition is not so evident to others, so we shall make some observations that render it more palatable.

In section 2, we revisit the inversion formulae (1.1) and (1.2). Viewed from an appropiate perspective, these formulae and Chen's applications of them are about all there is to ponder. But the proposition is not so evident to others, so we shall make some observations that render it more palatable.

That number theory, arithmetic, is the Queen of Mathematics is self-evident to number theorists, and a matter of aesthetics. It can be established or bolstered by appeal to Gauss [20] who said so. Indeed it can be argued that the analytic structure of the Riemann zeta function, defined for $\operatorname{Re}(s) > 1$ by the series

$$\zeta(s) = \sum_{n=1}^{\infty} n^{-s}, \quad (1.4)$$

and whether or not they are useful remains to be seen.

paper is no exception. The unfamiliar results reported may or may not be new,

for those values of s for which the integral converges, and by analytic continuation elsewhere. The Mellin inversion formula [24] establishes sufficient conditions for the inversion of the transform (1.5) by the contour integral

$$f(x) = \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} x^{-s} \tilde{f}(s) ds, \quad (1.6)$$

where the contour of integration is the line $\text{Re}(s) = c$, with c chosen so that the original integral defining the Mellin transform converges adequately for all points on the contour. In particular, the usual gamma function is the Mellin transform of the function e^{-x} , i.e.,

$$I(s) = \int_0^{\infty} x^{s-1} e^{-x} dx \quad (\text{Re}(s) > 0) \quad (1.7)$$

and so for any real, positive c ,

$$e^{-x} = \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} x^{-s} I(s) ds. \quad (1.8)$$

The Riemann zeta function can also be expressed in terms of a Mellin transform. If we multiply eq. (1.7) by n^{-s} , take $t = x/n$ as a new integration variable and sum over n from 1 to ∞ , we find that

$$\zeta(s) I(s) = \int_0^{\infty} \frac{t^{s-1} e^{-t} dt}{1 - e^{-t}} = -(s-1) \int_0^{\infty} t^{s-2} \log(1 - e^{-t}) dt \quad (\text{Re}(s) > 1). \quad (1.9)$$

The Riemann zeta function is the classic example of a *Dirichlet series* $\sum_{n=1}^{\infty} a_n n^{-s}$. If such a series converges at $s = s_0$, it converges to a holomorphic function for $\text{Re}(s - s_0) > 0$.

2. Inversion formulae

Taking the Mellin transforms of both sides of eqs (1.1) and (1.2), we find that these equations underlying Chen's analysis reduce to

$$\tilde{\alpha}(s) = \zeta(s) \tilde{\beta}(s) \quad (2.1)$$

Here \mathcal{Q} is a subset of \mathbb{Z}_d^d , with the point $m = \mathbf{0}$ excluded. Since the argument of

$$a(x) = \sum_{m \in \mathcal{Q}} B(x \sqrt{m_1^2 + m_2^2 + \dots + m_d^2}), \quad (2.6)$$

that
analogue of the inversion problem (1.1) is the determination of $B(x)$, given

Eq. (2.3) is very well known, but we indulge ourselves in providing it here. If we

$$\zeta(s) = \sum_{n=1}^{\infty} \mu(n) n^{-s}. \quad (2.3)$$

the assertion that
for appropriate a and b and $\operatorname{Re}(s) > 1$, Chen's result is equivalent to

$$B(s) = a(s) \sum_x \mu(n) n^{-s}, \quad (2.2)$$

and

β in eq. (2.6) is $x\sqrt{\text{integer}}$, by analogy with eqs (1.1) and (1.2), we seek an inversion formula of the form

$$\beta(x) = \sum_{k=1}^{\infty} \omega(k) \alpha(x\sqrt{k}) \quad \text{for all } x > 0. \quad (2.7)$$

Taking Mellin transforms of eqs (2.6) and (2.7), we find them to be equivalent provided that

$$\sum_{k=1}^{\infty} \omega(k) k^{-s/2} = \left(\sum_{m \in \Omega} (m_1^2 + m_2^2 + \cdots + m_d^2)^{-s/2} \right)^{-1}. \quad (2.8)$$

We can now expand the right-hand side in powers of $k^{-s/2}$, and equate coefficients of $k^{-s/2}$ to deduce the value of $\omega(k)$ for k as large as our patience permits.

We illustrate the technique for two examples where the summation variables are drawn from sets of points on the two-dimensional square lattice.

Example (i). A quadrant of the square lattice. Let

$$\alpha(x) = \sum'_{m,n=0}^{\infty} \beta(x\sqrt{m^2 + n^2}) \quad \text{for all } x > 0, \quad (2.9)$$

where the prime denotes the omission of the term corresponding to $m = n = 0$ from the sum. The coefficients $\omega(k)$ in the inversion formula (2.7) are given by

$$\sum_{k=1}^{\infty} \omega(k) k^{-s/2} = \left(\sum'_{m,n=0}^{\infty} (m^2 + n^2)^{-s/2} \right)^{-1}. \quad (2.10)$$

In table I, we show the values of $\omega(k)$ for $k \leq 30$. These can be generated on paper by brute force in a few minutes. In table II, we illustrate the inversion formula for the case $\beta(x) = e^{-x^2}$. For this choice of $\beta(x)$, the function $\alpha(x)$ is easily evaluated numerically. We now attempt to recover $\beta(x)$ using eq. (2.10). The results are shown in table II. It will be seen from table II that unless x is very small, only a few terms need to be taken to ensure an accurate approximation to $\beta(x)$.

Inspection of table I reveals some striking properties of the sequence $\omega(k)$. After a fairly innocuous beginning [$\omega(1) = \frac{1}{2}$, $\omega(2) = -\frac{1}{4}$, $\omega(3) = 0, \dots$], the values 0 and $-\frac{1}{2}$ are taken rather often, while

$$\omega(2^n) = (-1)^{n+1} 3/2^{n+1}, \quad n = 2, 3, 4, \dots \quad (2.11)$$

We seek an explanation for this. If we write $A(z) = \alpha(\sqrt{z})$ and $B(z) = \beta(\sqrt{z})$,

Table I
Coefficients $w(k)$ for the inversion of the two-dimensional lattice sum in example (i).

with $a \geq 0$ and $b \geq 0$, then eq. (2.12) becomes

$$A(x) = \sum_{n=1}^{\infty} \sum_{k=1}^{\infty} r_2^+(n) \omega(k) A(knx). \quad (2.13)$$

and if by $d | m$ we mean that d is a divisor of m (where 1 and m are regarded as divisors of m), then we may write

$$A(x) = \sum_{m=1}^{\infty} \sum_{d|m} r_2^+(m/d) \omega(d) A(mx). \quad (2.14)$$

We now see that the coefficients $\omega(k)$ must be chosen such that

$$r_2^+(1) \omega(1) = 1, \quad (2.15)$$

and for $m \geq 2$,

$$\sum_{d|m} r_2^+(m/d) \omega(d) = 0. \quad (2.16)$$

Since $r_2^+(1) = 2$, we infer at once that $\omega(1) = \frac{1}{2}$, while eq. (2.16) furnishes us with a recurrence relation, from which the entries in table I are easily calculated, as an alternative to the brute force calculation described in section 2. Moreover, the values of $\omega(k)$ for many values of k can be written down at once. Consider the case in which p is an odd prime number. Setting $m = p$ in eq. (2.16), since the divisors are $d = 1$ and $d = p$, we have $r_2^+(p) \omega(1) + r_2^+(1) \omega(p) = 0$, and since $\omega(1) = \frac{1}{2}$ and $r_2^+(1) = 2$,

$$\omega(p) = -\frac{1}{4} r_2^+(p). \quad (2.17)$$

It is trivial to verify that a prime of the form $4m + 3$ cannot be expressed as a sum of two integral squares. It can be shown (ref. [3], pp. 218–219) that a prime number of the form $4m + 1$ can be expressed as a sum of two integral squares in only one way, apart from the sign of the integers and their order in the sum, so that if $p = 4m + 1$ is prime, then $r_2^+(p) = 2$. Hence for any odd prime p ,

$$\omega(p) = \begin{cases} -\frac{1}{2}, & p = 4m + 1, \\ 0, & p = 4m + 3. \end{cases} \quad (2.18)$$

We can determine $\omega(k)$ for many other values of k . For example, if p and p' are distinct odd primes, then

$$L(z) = \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k+1)} z^{2k+1}. \quad (2.25)$$

where

$$\sum_{z=-\infty}^{\infty} (m_z + n_z) e^{-z} = 4L(z) G(z), \quad (2.24)$$

Titchmarsh [4] (p. 35), Hardy and Wright [3] (theorem 306) and Glasser [27] have shown that for $\operatorname{Re}(z) > 1$,

$$G(s) = \sum_{z=-\infty}^{\infty} (m_z + n_z) e^{-sz/2} F(s). \quad (2.23)$$

Mellin transform of both sides of eq. (2.22), we deduce that example (i) above, but we can in fact proceed somewhat further. If we take the from the sum. Here the inversion formula can be discovered exactly as in where the prime denotes the omission of the term corresponding to $m = n = 0$

$$a(x) = \sum_{z=-\infty}^{\infty} B(x \sqrt{m_z + n_z}) \quad \text{for all } x > 0, \quad (2.22)$$

Example (ii). The full square lattice. Let

The reader is invited to derive eq. (2.11) from eq. (2.16). Eq. (2.18) and (2.19) explain the frequent occurrence of 0 and $-\frac{1}{2}$ in table I.

Eq. (2.20) involves unequal, nonzero integers and it is clear that $r_2(n) = 4r_3(n)$. The form (2.20) is neither a perfect square nor twice a perfect square, all decompositions of n in integers of the form $4m + 3$ result in the same number of terms and the order of the decomposition is the same as for $4m + 1$ and $4m + 2$.

where $d_1(n)$ and $d_3(n)$ are the number of divisors of n of the form $4m + 1$ and

$$r_2(n) = 4[d_1(n) - d_3(n)], \quad (2.21)$$

is

$$x_1^2 + x_2^2 = n \quad (2.20)$$

theorem 278) that the number of integral solutions of the theory of elliptic functions (see e.g., ref. [26], or ref. [3]), from the analysis is simplified if one notes the classical result of Jacobi otherwise. The analysis is simplified if one notes the classical result of Jacobi and $w(2pp)$ takes only two values ($\frac{1}{2}$ if $p = 4m + 1$ and $p = 4m + 3$; 0

$$w(2p) = 0, \quad w(p) = -\frac{1}{2}, \quad w(pp) = 0, \quad (2.19)$$

Hence

$$\tilde{\beta}(s) = \frac{\tilde{\alpha}(s)}{4L(\frac{1}{2}s) \zeta(\frac{1}{2}s)}. \quad (2.26)$$

The function $L(z)$ (denoted by $\beta(z)$ in some texts) has been extensively studied [27]. It governs the distribution of prime numbers in the progression $4m+1$ and $4m+3$. Its values are known for the odd positive integers, for example $L(1) = \frac{1}{4}\pi$ and $L(3) = \frac{1}{32}\pi^3$, while $L(2) \approx 0.916$ defines Catalan's constant.

To effect the inversion of eq. (2.22) as a double sum, we write

$$\frac{1}{L(s)} = \sum_{m=1}^{\infty} \bar{\omega}(m) m^{-s} \quad (2.27)$$

and use eq. (2.3) to deduce that

$$\tilde{\beta}(s) = \frac{1}{4} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{\bar{\omega}(m) \mu(n) \tilde{\alpha}(s)}{m^{s/2} n^{s/2}}. \quad (2.28)$$

Inverting the Mellin transform, we deduce that

$$\beta(x) = \frac{1}{4} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \bar{\omega}(m) \mu(n) \alpha(x\sqrt{mn}). \quad (2.29)$$

We now need a recipe for computing the coefficients $\bar{\omega}(m)$. If $\varphi(m)$ is a completely multiplicative function of positive integers m and n , in the sense that

$$\varphi(m) \varphi(n) = \varphi(mn), \quad (2.30)$$

then, where the product over p is taken over all prime numbers,

$$\sum_{m=1}^{\infty} \varphi(m) m^{-s} = \prod_p [1 - \varphi(p) p^{-s}]^{-1}, \quad (2.31)$$

provided that the series on the left-hand side converges absolutely (ref. [28], p. 168). The proof of this is a simple generalization of the proof of eq. (2.5). If we write

$$L(s) = \sum_{m=1}^{\infty} \varphi(m) m^{-s}, \quad (2.32)$$

then $\varphi(2k) = 0$ and $\varphi(2k-1) = (-1)^{k-1}$. It is easily verified that in this case eq.

and for $m \geq 2$,

$$r_2(1) \omega(1) = 1, \quad (2.40)$$

where $r_2(n)$ is given by eq. (2.21). We now see that the coefficients $\omega(k)$ must be chosen such that

$$A(x) = \sum_{m=1}^{\lfloor x \rfloor} \sum_{d|m} r_2(m/d) \omega(d) A(mx), \quad (2.39)$$

imitating the analysis which led to eq. (2.14), we have

Even if we had not seen how to find the explicit formula (2.38) for $\omega(k)$,

$$\omega(k) = \frac{1}{4} \sum_{d|k} \omega(d) \mu(k/d) = \frac{1}{4} \sum_{d|k} |\mu(d)| \mu(k/d) (-1)^{\epsilon(m)}. \quad (2.38)$$

If we change the summation indices in eq. (2.29), we may write the inversion formula in the form (2.7), where

$$\omega(m) = |\mu(m)| (-1)^{\epsilon(m)} \quad (m \text{ odd}). \quad (2.37)$$

If, as above, $d_2(n)$ denotes the number of divisors of n of the form $4m+3$, we may rewrite eq. (2.35) as

$$\omega(m) = k_1 + k_2 + \dots + k_m, \quad (2.36)$$

where

$$\omega(m) = (-1)^{\epsilon(m)}, \quad (2.35)$$

where m has exactly M distinct prime factors, then

$$m = (2k_1 - 1)(2k_2 - 1) \cdots (2k_M - 1), \quad (2.34)$$

where $\omega(1) = 1$ and $\omega(m)$ is zero for $m \geq 2$ unless m is the product of distinct odd prime numbers (so that if m is even, or if $\mu(m) = 0$, then $\omega(m) = 0$). For those m where $\omega(m)$ is nonzero, if we write

$$\frac{L(s)}{1} = \prod_p \left[1 - \phi(p)p^{-s} \right] = \sum_{m=1}^{\infty} \omega(m) m^{-s}, \quad (2.33)$$

(2.30) holds, so that

$$\sum_{d|m} r_2(m/d) \omega(d) = 0, \quad (2.41)$$

so that the determination of extravagantly many coefficients is straightforward.

We have not discussed here the generalization of our analysis to higher-dimensional problems. The basic Mellin transform procedure and subsequent brute-force determination of the coefficients analogous to $\omega(k)$ in examples (i) and (ii) is evidently applicable. For hypercubic lattices, we can also exploit some number-theoretic results, since the number $r_k(n)$ of integral solutions of $x_1^2 + x_2^2 + \cdots + x_k^2 = n$ has been extensively studied, with a classical solution of Jacobi available for the cases $k = 2, 4, 6$ and 8 , and solutions of Ramanujan and others covering even k for $k \leq 24$ (ref. [26], ch. IX). For odd k , the analysis is more difficult, but some references can be found in pp. 157–158 of ref. [26].

3. Tautologies

Consider now the generalised zeta function, defined for $\operatorname{Re}(s) > 1$ and $0 < a \leq 1$ by the series

$$\zeta(s, a) = \sum_{n=0}^{\infty} (n+a)^{-s}. \quad (3.1)$$

With this definition,

$$\zeta(s, 1) = \zeta(s). \quad (3.2)$$

We claim that the definition of $\zeta(s, a)$ is equivalent to the theory of integration [29] and therefore the calculus. To see this, note that from the binomial theorem

$$(n+a)^{-s} = n^{-s} \sum_{m=0}^{\infty} \frac{(-1)^m s(s+1)\cdots(s+m-1)a^m}{m!n^m}, \quad (3.3)$$

so that inserting this into the summand in eq. (3.1) and interchanging the orders of summation, we have the identity

$$\begin{aligned} \zeta(s, a) &= a^{-s} + \zeta(s) - sa\zeta(s+1) + \frac{s(s+1)a^2}{2!} \zeta(s+2) \\ &\quad - \frac{s(s+1)(s+2)a^3}{3!} \zeta(s+3) + \cdots, \end{aligned} \quad (3.4)$$

orders of summation, we have

Replacing $1/\zeta(s+m+1)$ with the series $\sum_{n=1}^{\infty} \mu(n) n^{-s-m-1}$ and interchanging

$$(3.9) \quad \sum_{n=1}^{\infty} \frac{\zeta(s+m+1) \mu(n)}{(-1)^m \zeta(s+m) \zeta(s+1)} =$$

$$(3.8) \quad \zeta(s, a) - a^{-s} = \sum_{m=0}^{\infty} \frac{m!}{(-1)^m \zeta(s+m) a^m}$$

we have

$$(3.7) \quad (s)_n = s(s+1) \cdots (s+n-1) = F(s+n)/F(s).$$

An interesting result can be obtained from eq. (3.4). If we write for brevity Riemann is fundamental and central to all analysis.

important that one sees through such considerations is that the zeta function of

which is the more fundamental way to view matters is immaterial. What is

delta function and other generalized functions automatically.

integral gives directly analytic continuation and includes integration over the special case of an infinite partition. This more general definition of an Riemann's which is an asymptotic expansion. (The Riemann integral is remainder series which is a sum over an arbitrary finite partition together with a Riemann integral as a sum over an arbitrary finite partition together with a remainder from them [29]. The theory so obtained gives an extension of the usual Leibniz's theory of integration (and differentiation and interpolation) can be derived a theory of integration (and differentiation and interpolation) can be

The apparently trivial identities (3.1)-(3.5) are in reality quite profound.

for some similar formulae.

Bernoulli polynomials (ref. [30], p. 267). We refer the reader to ref. [4], p. 33.

From eq. (3.4) we can obtain the standard expression for $\zeta(-n, a)$ in terms of

for some similar formulae.

By assuming this identity holds for all s , we have

$$(3.5) \quad \lim_{s \rightarrow 0} s\zeta(1+s) = 1, \quad \zeta(0) = -\frac{1}{2}, \quad \zeta(-1) = -\frac{1}{12}, \quad \zeta(-2) = 0, \dots$$

Setting $a = 1$ we have the remarkable identity

manipulations are valid, but which hold more generally by analytic con-

tinuation.

which we establish originally for those values of s for which the series

manipulations are valid, but which hold more generally by analytic con-

tinuation.

which we establish originally for those values of s for which the series

manipulations are valid, but which hold more generally by analytic con-

tinuation.

$$\zeta(s, a) - a^{-s} = \sum_{n=1}^{\infty} \frac{\mu(n)}{n} \sum_{m=0}^{\infty} \frac{(-1)^m \zeta(s+m) \zeta(s+m+1) (s)_m a^m}{n^{s+m} m!}. \quad (3.10)$$

If we replace s by $s+1$ in eq. (1.9), we obtain

$$\zeta(s+1) = -\frac{1}{\Gamma(s)} \int_0^{\infty} t^{s-1} \log(1 - e^{-t}) dt. \quad (3.11)$$

Now letting $t = kx$, and summing over k , we produce the identity

$$\zeta(s) \zeta(s+1) = -\sum_{k=1}^{\infty} \frac{1}{\Gamma(s)} \int_0^{\infty} x^{s-1} \log(1 - e^{-kx}) dx \quad (3.12)$$

$$= -\frac{1}{\Gamma(s)} \int_0^{\infty} x^{s-1} \log\left(\prod_{k=1}^{\infty} (1 - e^{-kx})\right) dx \quad (3.13)$$

$$= -\frac{n^s}{\Gamma(s)} \int_0^{\infty} x^{s-1} \log\left(\prod_{k=1}^{\infty} (1 - e^{-nkx})\right) dx. \quad (3.14)$$

This identity (with s replaced by $s+m$) can now be used, together with eq. (3.7), to eliminate $\zeta(s+m) \zeta(s+m+1) (s)_m$ from eq. (3.9). When this is done, the sum over m can be recognized as an exponential, giving

$$\Gamma(s) [\zeta(s, a) - a^{-s}] = -\sum_{n=1}^{\infty} \frac{\mu(n)}{n} \int_0^{\infty} x^{s-1} e^{-nx} \log\left(\prod_{k=1}^{\infty} (1 - e^{-nkx})\right) dx. \quad (3.15)$$

This formula illustrates another connection that will recur below, namely the intimate connection between the generalised zeta function and Euler's product

$$F_E(x) = \prod_{k=1}^{\infty} (1 - x^k), \quad (3.16)$$

which is central to the theory of partitions and the theory of elliptic modular functions [26]. We may view eq. (3.15) as a "totem pole" for the higher transcendental functions, just as the wonderful formula $e^{i\pi} = -1$ may be regarded as a "totem pole" for the elementary transcendental functions.

By manipulating the inversion formulae (2.1) and (2.2), which reduce to the tautology

If we represent $\phi(x)$ as an inverse Mellin transform and translate the contour of integration across two poles, use of the Riemann relation and a change of

$$\phi(x) = \sum_{m=1}^{\infty} e^{-mx}. \quad (3.23)$$

where

$$\phi(x) = x^{-\frac{1}{2}} [\phi(1/x) + \zeta - \frac{1}{x}] \quad (x < 0), \quad (3.22)$$

(more succinctly described as the *Riemann relation*) and a transformation from the theory of theta functions,

$$\zeta(s) = 2 \cdot \pi^{-\frac{1}{2}} \sin(\frac{\pi}{2} s) F(1-s) \zeta(1-s) \quad (3.21)$$

this is furnished by the functional equation for the Riemann zeta function thatologies can be proved to be precisely equivalent. The canonical example of (1.6), can be a source of similar tautologies. Many superficially unrelated such as the familiar Fourier integral theorem or the Mellin inversion theorem obtained by playing around with series and integrals. Any inversion formula, the formulae produced in this section are examples of "fruitful tautologies".

$$\sum_n \frac{1}{a_n z^n} = \sum_n b_n z^n \quad \text{if and only if} \quad \zeta(s) \sum_n a_n n^{-s} = b_n. \quad (3.20)$$

is actually a special case of a known result for Lambert series [3]. The reader is invited to set $z = e^{-x}$ and take Mellin transforms to deduce that

$$z = \sum_n \frac{1}{\mu(n)} \frac{1}{n^x}. \quad (3.19)$$

Neither of the results (3.15) and (3.18) would be deemed obvious by the casual reader, yet the proofs of them have required only some elementary manipulations of series and integrals. Eq. (3.18), when rewritten in the form

$$e^{-x} = \sum_{n=1}^{n=\infty} \frac{1}{\mu(n)} e^{-nx}. \quad (3.18)$$

example, we can produce additional bizarre formulae involving the Möbius function, for

$$\alpha(x) = \sum_{m=1}^{m=\infty} \sum_{n|x} \mu(n) \alpha(mn) \quad \text{for all } x > 0, \quad (3.17)$$

integration variable produces an inverse Mellin transform which can be recognized as $x^{-1/2}\phi(1/x)$, so that the Riemann relation (3.21) implies eq. (3.22). There are eight different proofs of the Riemann relation in ref. [4]. One of these commences with eq. (3.22), so that eq. (3.22) implies the Riemann relation (3.21). It is purely a matter of taste which of the two formulae is the more fundamental, and each can be derived in other ways apparently without reference to the other.

In section 8, we uncover some further tautologies, arising from the equivalence of certain sums of delta functions with divergent sums of cosines, interpreted within the sense of Lighthill's presentation of generalized functions. The simplest prototype of these results is the identity (ref. [31], pp. 67–68)

$$\sum_{m=-\infty}^{\infty} \delta(x-m) = \sum_{m=-\infty}^{\infty} e^{2\pi mx i}. \quad (3.24)$$

This is the generalized function statement of the Poisson summation formula

$$\sum_{m=-\infty}^{\infty} P(m) = \sum_{m=-\infty}^{\infty} \int_{-\infty}^{\infty} P(x) e^{2\pi mx i} dx, \quad (3.25)$$

and is equivalent to the classical formula for the determination of the coefficients in a Fourier series. Either of eqs. (3.24) or (3.25) can be used to derive the Riemann relation (3.21) and the theta function transformation (3.22). Bellman [21], pp. 34–36, has obtained the Poisson summation formula as a consequence of the Riemann relation, remarking that this "shows what is so often true in analysis, namely that it is not easy to distinguish between the general and the particular". The Riemann relation, the theta function transformation, Poisson's summation formula and the key results of the theory of Fourier series are all manifestations of the same tautology.

4. Prime and natural gases

In the preceding discussion, we have been preoccupied with the Riemann zeta function (1.4), Euler's infinite product representation of it, (2.5), and some consequences, producing connections with Euler's product (3.16) and other fruitful mathematical tautologies. Here we wish to make contact with physics, with examples drawn from statistical mechanics. The Riemann zeta function is paramount in the statistical mechanics of Bose–Einstein gases [32] and in the examples which follow it is also pre-eminent. Some of these considerations have been anticipated by Mackey [33] and by Julia [34, 35], and

12, ref. [36], p. 5)

Using the infinite product representation of $\zeta(s)$ one readily obtains (ref. [4], p.

$$\sum_n \exp(-\beta e_n) = \prod_n \frac{1}{1 - e^{-\beta e_n}}. \quad (4.6)$$

For the prime gas (4.3), where p now denotes a generic prime number,

single-particle states grows exponentially in the energy.

This singular behavior, discussed further below, results because the density of states, such as the internal energy and heat capacity, can be obtained from eqs (4.1) and (4.4) in the usual way. They will all become singular as $T \rightarrow T_{\max}$. All the thermodynamic properties, such as the maximum allowable temperature. All the thermodynamic prop-

$$T_{\max} = e_0/k \quad (4.5)$$

The partition function diverges for all $T \gg T_{\max}$, where

$$\sum_n \exp(-\beta e_n) = \zeta(\beta e_0) \quad \text{when } \beta e_0 < 1. \quad (4.4)$$

For the natural gas (4.2), we find readily that

where e_0 is a positive parameter with the dimensions of energy.

$$e_n = \begin{cases} e_0 \log n, & n \text{ prime } (2, 3, 5, 7, 11, \dots), \\ \infty, & \text{otherwise,} \end{cases} \quad (4.3)$$

the "prime gas"

$$e_n = \begin{cases} e_0 \log n, & n \text{ a natural number } (1, 2, 3, \dots), \\ \infty, & \text{otherwise.} \end{cases} \quad (4.2)$$

the "natural gas"

where $\beta = (kT)^{-1}$, with T the absolute temperature and k Boltzmann's constant. We consider the following two single-particle spectra:

$$Q_N(T) = \frac{N!}{1} \left(\sum_n \exp(-\beta e_n) \right)^N, \quad (4.1)$$

particles with single-particle excitation spectrum e_n is [32].

The canonical partition function for a classical gas of N non-interacting particles especially illuminating.

they become especially illuminating.

no doubt other persons unknown to us, but in the context of the present paper,

$$\log \zeta(s) = \sum_p \sum_{m=1}^{\infty} \frac{1}{mp^{ms}} = \sum_p \frac{1}{p^s} + R_1(s), \quad (4.7)$$

where

$$R_1(s) = \sum_p \sum_{m=2}^{\infty} \frac{1}{mp^{ms}} \quad (4.8)$$

is holomorphic for $\operatorname{Re}(s) > \frac{1}{2}$. Indeed (ref. [36], p. 5), for $\operatorname{Re}(s) \geq 1$,

$$|R_1(s)| \leq \frac{\zeta(2s)}{2(1 - 2^{-s})}, \quad (4.9)$$

so that $|R_1(s)| \leq \zeta(2) = \frac{1}{6}\pi^2$ for $\operatorname{Re}(s) \geq 1$. It is interesting to note that, in the spirit of the totem pole (3.15),

$$\sum_p \frac{1}{p^s} = \sum_{n=1}^{\infty} \frac{\mu(n)}{n} \log \zeta(ns) \quad (4.10)$$

(ref. [4], p. 12). Thus we find that as $\beta\epsilon_0 \rightarrow 1^+$,

$$\sum_n \exp(-\beta\epsilon_n) = \sum_p \frac{1}{p^{\beta\epsilon_0}} \sim \log \zeta(\beta\epsilon_0) \sim \log[(\beta\epsilon_0 - 1)^{-1}]. \quad (4.11)$$

Once again there is a maximum allowable temperature T_{\max} , given by eq. (4.5) above. Since the singular behaviour at T_{\max} is weaker than that for the natural gas, the corresponding thermodynamic properties will have weaker (though more exotic) singular behaviour. The singularity in the partition function is weaker for the prime gas as a direct consequence of the asymptotic density of the prime numbers. Since the number $\pi(x)$ of prime numbers less than or equal to x grows as $x/\log x$, from the prime number theorem [4, 36], the single particle density of states for the prime gas is effectively $1/\log x$, while that for the natural gas is unity.

At this point it is of more than passing interest to ask if any physical system can exhibit a maximum allowable temperature. Hagedorn [37] has developed a fascinating statistical-thermodynamic “fireball” model of hadron (elementary particle) physics and a maximum allowable temperature arises for comparable reasons as in the prime and integer gases. In particle physics, the maximum allowable temperature has become known as the Hagedorn temperature, and it appears in all fundamental microscopic theories of hadron physics. We briefly re-encounter hadron physics in a different context in section 6 below.

Proceeding now to quantum statistical mechanics, the canonical partition function for a gas of non-interacting, non-number-conserved particles with single particle spectrum ϵ_n is

contributes a constant to $\log Q^F(T)$. We have $n = 1$, though this is not essential here, as the inclusion of the ground state only For the fermion case of the natural gas, we again exclude the ground state is holomorphic for $\text{Re}(s) \geq 1$, and $|R^z(s)| \leq |\zeta(2s) - 1|/[2(1 - 2^{-s})] \leq$

$$R^z(s) = \sum_{n=2}^{\infty} \sum_{m=2}^{mn} \frac{1}{1}, \quad (4.17)$$

where

$$\log Q^B(T) = \sum_{n=2}^{\infty} \sum_{m=1}^{mn} \frac{1}{1} = \zeta(B_{E^0}) - 1 + R^z(B_{E^0}), \quad (4.16)$$

duced eq. (4.7), we have excluded. With this modification, by a similar procedure to that which produced. For the boson case of the natural gas, the ground state $n = 1$ must be excluded. For the fermi case of the natural gas, the ground state $n = 1$ must be excluded.

$T = T_{\max}$) follow by the usual arguments. and all thermodynamic properties (which are correspondingly singular at $T = T_{\max}$) given by eq. (4.5). Once again there is the Hagedorn phenomenon, with T_{\max} given by eq. (4.5),

$$Q^F(T) = \frac{\zeta(2B_{E^0})}{\zeta(B_{E^0})}, \quad \text{for } B_{E^0} < 1, \quad (4.15)$$

and (cf. eq. (7.2) below)

$$Q^B(T) = \zeta(B_{E^0}), \quad \text{for } B_{E^0} > 1, \quad (4.14)$$

For the prime gas (4.3), we readily verify that neutinos in conventional quantum field theory. Such non-number-conserved particles are to be considered as quantized excitations of some appropriate Bose or Fermi fields, such as the photons and

$$Q^F(T) = \prod_n [1 + \exp(-B_{E^n})], \quad (4.13)$$

for fermions

$$Q^B(T) = \prod_n [1 - \exp(-B_{E^n})], \quad (4.12)$$

for bosons

$$\log Q_F(T) = \sum_{n=2}^{\infty} \sum_{m=1}^{\infty} \frac{1}{mn^{m\beta\epsilon_0}} - \sum_{n=2}^{\infty} \sum_{m=1}^{\infty} \frac{1}{mn^{2m\beta\epsilon_0}} \quad (4.18)$$

$$= \zeta(\beta\epsilon_0) - \zeta(2\beta\epsilon_0) + R_3(\beta\epsilon_0), \quad (4.19)$$

where $R_3(s)$ is holomorphic for $\text{Re}(s) \geq 1$ and readily bounded. It will come as no surprise to the reader that for both the boson and fermion natural gases, the Hagedorn phenomenon again appears. We remark that to obtain precise results for the thermodynamic functions near the Hagedorn temperature, we need an expansion of $\zeta(s)$ in the vicinity of $s = 1$, viz.

$$\zeta(s) = \frac{1}{s-1} + \gamma + \sum_{k=1}^{\infty} \frac{(-1)^k c_k}{k!} (s-1)^k, \quad (4.20)$$

where $\gamma \approx 0.5772$ is Euler's constant. The expansion (4.20) was first published in 1885 by Stieltjes. It is the Laurent series for the Riemann zeta function, and so is convergent for all $s \neq 1$. The reader is referred to p. 164 of the first volume of Ramanujan's notebooks, edited by Berndt [11], for some intriguing material and accurate numerical values for the first few coefficients c_k .

In closing this section, we note that if we imitate Planck by neglecting zero point energy and writing the single-particle spectrum for black body radiation as

$$\epsilon_n = n\hbar\omega, \quad (4.21)$$

then omitting the ground state $n = 0$, we have for the Bose and Fermi cases respectively

$$Q_B(T) = \prod_{n=1}^{\infty} (1 - x^n)^{-1} = \frac{1}{F_E(x)} \quad (4.22)$$

and

$$Q_F(T) = \prod_{n=1}^{\infty} (1 + x^n) = \frac{F_E(x^2)}{F_E(x)}, \quad (4.23)$$

where $x = \exp(-\beta\hbar\omega)$ and $F_E(x)$ is Euler's infinite product (3.16), which we have already encountered in the totem pole (3.15), which is the cornerstone of the theory of partitions [26] and which figures prominently in section 6 below. The study of quantum field theory is sufficiently well advanced that one could easily approach these problems without explicit reference to the classical analysis which underlies them, but we feel that one is the poorer if deprived of the rich mathematical antecedents.

$$g_2(x) = \sum_{n=-\infty}^{\infty} \frac{1}{2\pi i} \int_{c+i\infty}^{c-i\infty} e^{-ns} (x_{-s} - 1) h(s) ds, \quad (5.7)$$

and

$$g_1(x) = \sum_{n=0}^{\infty} \frac{1}{2\pi i} \int_{c+i\infty}^{c-i\infty} e^{-ns} (x_{-s} - 1) h(s) ds \quad (5.6)$$

If we write

$$h(s) = \frac{s}{h(0_+)} + \text{a function holomorphic in } -\epsilon < \operatorname{Re}(s) < \epsilon, \quad (5.5)$$

be

where $h_2(s) < \epsilon$. The analytic continuation of $h(s)$ is easily seen from eq. (5.2) to $0 < \operatorname{Re}(s) < \epsilon$. The Mellin transform of h , which is holomorphic in the strip

$$g(x) = \sum_{n=-\infty}^{\infty} \frac{1}{2\pi i} \int_{c+i\infty}^{c-i\infty} e^{-ns} (x_{-s} - 1) h(s) ds \quad (0 < c = \operatorname{Re}(s) < \epsilon), \quad (5.4)$$

the same functional equation as $\log x$, and $g(1) = 0$. Perhaps, then, our plausible conjecture, we use the relation (1.6) to deduce that

$$g(ex) = g(x) + g(e), \quad (5.3)$$

The series converges uniformly for all finite closed subintervals of $(0, \infty)$, so that $g(x)$ is continuous for $x > 0$. Obviously $g(x)$ satisfies the functional equation

$$h(x) = h(0_+) + O(x_\epsilon) \quad \text{as } x \rightarrow 0_+ \quad \text{and} \quad h(x) = O(1/x) \quad \text{as } x \rightarrow \infty, \quad (5.2)$$

where h is a continuous function for $0 \leq x < \infty$ and for some $\epsilon > 0$,

$$g(x) = \sum_{n=-\infty}^{\infty} [h(xe_n) - h(e_n)], \quad (5.1)$$

Consider the function $g(x)$, defined for $x > 0$ by the series

5. Functional equations and scaling relations

then

$$g(x) = g_1(x) + g_2(x). \quad (5.8)$$

Since the series defining $g_1(x)$ converges uniformly with respect to s on the integration contour, we can interchange orders of integration and summation to obtain

$$g_1(x) = \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} \frac{(x^{-s}-1)\tilde{h}(s) ds}{1-e^{-s}} \quad (c = \operatorname{Re}(s) > 0). \quad (5.9)$$

The interchange is not permissible in the series defining $g_2(x)$, but we can overcome the problem, by observing that the integrand has no pole at $s=0$, the pole of $\tilde{h}(s)$ being cancelled by the zero of $(x^{-s}-1)$. Therefore we may translate the contour to the left to write

$$g_2(x) = \sum_{n=1}^{\infty} \frac{1}{2\pi i} \int_{c'+i\infty}^{c'-i\infty} e^{ns}(x^{-s}-1)\tilde{h}(s) ds \quad (-1 < c' = \operatorname{Re}(s) < 0), \quad (5.10)$$

and on the new contour our sum converges uniformly so that we can perform the interchange to produce

$$g_2(x) = -\frac{1}{2\pi i} \int_{c'-i\infty}^{c'+i\infty} \frac{(x^{-s}-1)\tilde{h}(s) ds}{1-e^{-s}} \quad (-1 < c' = \operatorname{Re}(s) < 0). \quad (5.11)$$

We thus deduce that

$$g(x) = \frac{1}{2\pi i} \int \frac{(x^{-s}-1)\tilde{h}(s) ds}{1-e^{-s}}, \quad (5.12)$$

where the integration contour (traversed anticlockwise) encircles the imaginary axis. The singularities enclosed are simple poles at $s=0$ and at $s=\pm 2n\pi i$ ($n=1, 2, \dots$). Summing over the residues we obtain

$$g(x) = -h(0^+) \log x + \sum_{\substack{n=-\infty \\ n \neq 0}}^{\infty} \tilde{h}(2\pi in)(x^{-2\pi in}-1). \quad (5.13)$$

The reader offended by the informality of the argument here will easily supply the appropriate rigorous argument involving an expanding sequence of rectangles with corners at the points $c \pm (2n+1)\pi i$, $c' \pm (2n+1)\pi i$.

and many testicular glass oil tuberculins.

An unperturbed electron motion of eq. (3.16) due to one of the authors, which serves as the prototype for the present general discussion, was briefly reproduced in ref. [42]. The analysis can be extended to account for the transformation of the series \mathcal{E}_n , \mathcal{Z}_n , $[h(x)]$, $-[h(x)]$, for a multi-dimensional case of functions h .

we convert the linear functional equation (3.3) into the nonlinear functional equation

$$(5.17) \quad x \equiv e \quad \text{and} \quad g(x) = 1/N(t),$$

If we write

stable for $x > 0$.

Computational [M.1]: Bivariate, personal communication] shows that in addition to $x = c$, there exists another infinite set of real zeros of $g(x) + \log x$. Although the function $g(x) + \log x$ is self-similar, it is not fractal in the sense of Mandelbrot, for it is everywhere continuous and everywhere infinitely differentiable.

$$(5.16) \quad \sum_{\substack{0 \neq u \\ x-u}} F(\mathcal{Z}\min)(x_{\tilde{\gamma}^{u,0}} - 1).$$

for which $h(s) = F(s)$ and eq. (5.13) becomes

$$(\xi_1, \xi_2) = (\xi_1^1, \xi_1^2, \dots, \xi_1^n, \xi_2^1, \xi_2^2, \dots, \xi_2^n)$$

Our function $g(x)$ does coincide with $-h(0_+)$ for x at isolated points where $(x - 2m - 1) = 0$ for all n , i.e., $x = e^m$ ($m = 0, \pm 1, \pm 2, \dots$). In between $g(x)$ wobbles about the function $-h(0_+)$. A similar problem led Ramanujan to his fallacious proof of the prime number theorem. He forgot the wobblies (ref [26], pp. 38–39). Our problem is really much deeper than it appears. Consider the special case #3.

$\log x$ with period 1. Hughes et al. [38, 39] have encountered a periodic function of x , which exhibits some similar features, or a periodic function of x , which is more complicated than this in the context of the Fourier analysis of a random walk with self-similar clusters. Analogies between this random walk and the renormalization problem have been discussed by Shlesinger and Huges [40]. For some mathematical problems in hierarchical models, see ref. [41].

$\langle t_1 \rangle \Delta = \langle x_2 \rangle \Delta$

A limit into the structure of $g(x)$ can actually be obtained by much simpler arguments. If we write $g(x) = -h_0(0^+)$, then

$$N(t+1) = \frac{N(t)}{1 - g(e) N(t)}. \quad (5.18)$$

For the special case (5.15), $g(e) = -1$, while more generally $g(e) = -h(0^+)$. Our analysis therefore produces solutions to the nonlinear difference equation which, although simple for integer values of t , behave somewhat irregularly for intermediate values of t . It is natural to speculate that some other nonlinear difference equations which produce chaotic solutions may be manifestations of tautologies in the spirit of eq. (5.13).

6. Euler's product

Consider now Euler's product $F_E(x)$ defined by eq. (3.16) above and write

$$f(x) = -\log F_E(x) = -\sum_{k=1}^{\infty} \log(1-x^k). \quad (6.1)$$

From eq. (3.13),

$$\Gamma(s) \zeta(s) \zeta(s+1) = -\sum_{k=1}^{\infty} \int_0^x x^{s-1} \log(1-e^{-kx}) dx, \quad (6.2)$$

so that

$$\Gamma(s) \zeta(s) \zeta(s+1) = \int_0^{\infty} x^{s-1} f(e^{-x}) dx, \quad (6.3)$$

and so by the Mellin inversion formula

$$f(e^{-x}) = \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} x^{-s} \Gamma(s) \zeta(s) \zeta(s+1) ds \quad (c = \operatorname{Re}(s) > 1). \quad (6.4)$$

The only pole of $\zeta(s)$ is at $s = 1$, near which

$$\zeta(s) = (s-1)^{-1} + \gamma + \dots, \quad (6.5)$$

where $\gamma = -\Gamma'(1)$ is Euler's constant, while $\Gamma(s)$ has a simple pole of residue $(-1)^n/n!$ at $s = -n$ ($n = 0, 1, 2, \dots$). The integral therefore has a double pole at $s = 0$ and simple poles at $s = \pm 1$. The remaining poles of the gamma function are cancelled by zeros of one or other of the zeta functions, since $\zeta(-2n) = 0$

It is fair to ask if the elegant mathematics leading to eq. (6.10) has any

$$G(x) = C(1/x). \quad (6.12)$$

then we have

$$G(x) = x^{1/4} e^{-\pi x/12} F^E(e^{-2\pi x}), \quad (6.11)$$

We can rewrite this remarkable formula in a different form, which reduces to a symmetry under inversion. If we define

$$F^E(e^{-x}) = \left(\frac{x}{2\pi}\right)^{1/2} \exp\left(\frac{x}{\pi} - \frac{6x}{\pi^2}\right) F^E(e^{-4\pi^2/x}). \quad (6.10)$$

Taking exponentials of both sides and recalling the definition of Euler's product $F^E(x)$, we deduce that

$$f(e^{-x}) = -\frac{24}{x} + \frac{6x}{\pi^2} + \frac{1}{2} \log\left(\frac{2\pi}{x}\right) + f(e^{-4\pi^2/x}). \quad (6.9)$$

Using well-known values of the Riemann zeta function ($\zeta(-1) = -\frac{1}{12}$ and $\zeta(0) = -\frac{1}{2}$, briefly derived in section 2, $\zeta(2) = \frac{\pi^2}{6}$ and $\zeta'(0) = -\frac{1}{2} \log(2\pi)$) we deduce that

$$I^R = f(e^{-4\pi^2/x}). \quad (6.8)$$

At first sight the first three terms in eq. (6.6) give us our product explicitly: However the remaining integral I^R does not vanish in this case, a circumstance connected with the curious properties of the zeta function at infinity. The integral I^R can be evaluated by transforming to a new integration variable $z = -s$, using the Riemann relation (3.21) on both zeta functions and removing a part of gamma functions using the reflection formula $F(s) F(1-s) = \pi/\sin(\pi s)$ to yield

$$I^R = \frac{1}{2\pi i} \int_{c+ix}^{c-ix} x^{-s} I(s) \zeta(s) \zeta(s+1) ds \quad (c = \text{Re}(s) > -1). \quad (6.7)$$

where

$$f(e^{-x}) = -\zeta(0) \zeta(-1) x - \zeta(0) \log x + \zeta(0) + \zeta(2)/x + I^R, \quad (6.6)$$

for $n = 1, 2, 3, \dots$. Evaluating the residues at the poles, we have

applications. The significance of Euler's product in number theory is discussed by Hardy [26] (chs. VI and VIII). Let $p_U(n)$ denote the number of *unrestricted partitions* of the integer n , i.e. the number of ways in which n can be expressed as a sum of positive integers (not necessarily distinct), without regard to order and let $p_D(n)$ denote the number of partitions of n into *distinct* positive integers. Then it can be shown that

$$F_E(x)^{-1} = 1 + \sum_{n=1}^{\infty} p_U(n) x^n, \quad (6.13)$$

$$\frac{F_E(x^2)}{F_E(x)} = 1 + \sum_{n=1}^{\infty} p_D(n) x^n, \quad (6.14)$$

and also that

$$F_E(x) = 1 + \sum_{k=1}^{\infty} (-1)^k (x^{k(3k-1)/2} + x^{k(3k+1)/2}). \quad (6.15)$$

The asymptotic forms of $p_U(n)$ and $p_D(n)$ have applications in the theory of the self-avoiding walk [43] and the spiral self-avoiding walk [44], and eq. (6.11) is used in the rigorous derivation of these forms [45]. Also, the function $x^{1/24} F_E(x)^{-1}$ and the coefficients of x in the expansion of $F_E(x)^{-24}$ appear in relativistic string theory [46, 47]. Eqs. (6.13)–(6.15) are not far from the theory of the Rogers–Ramanujan identities, which have been found useful lately in the analysis of two-dimensional lattice statistical mechanics problems [10, 48]. The function $F_E(x)^{-1}$ is, to quote Hardy [26], “one of a well-known class, the elliptic modular functions, whose properties have been studied intensively and are very exactly known . . . These functions all have the same peculiarities . . . and exist only inside the [unit] circle . . .”. Ramanujan's function $\tau(n)$ is defined by the equation (ref. [26], ch. X)

$$xF_E(x)^{-24} = \sum_{n=1}^{\infty} \tau(n) x^n. \quad (6.16)$$

and it is satisfying to see from the preceding references that this bizarre function, for which

$$\sum_{n=1}^{\infty} \tau(n) n^{-s} = \prod_p [1 - \tau(p) p^{-s} + p^{11-2s}]^{-1} \quad (6.17)$$

(where p is a prime number), may have [14] more than recreational interest.

Other tautologies can be constructed for Euler's product. It can be shown (ref. [4], p. 8) that for $\operatorname{Re}(s) > \max[1, \operatorname{Re}(a) + 1]$,

Expanding the logarithm and noting that $|\mu(m)| = |\mu(m)|$, we have

$$T^{\pm}(x, z) = \mp \sum_{\infty}^{m=1} \log[1 \mp |\mu(m)| z \exp(-mx)]. \quad (7.3)$$

For a less obvious example, consider (7.1) have Mellin transform $F(s) \zeta(s)$. (Eq. (7.2) is a simple consequence of eq. (2.5).) All three expressions in eq.

$$\sum_{\infty}^{m=1} |\mu(m)| = \frac{\zeta(2s)}{\zeta(s)}, \quad \operatorname{Re}(s) > 1. \quad (7.2)$$

Eqs. (1.4), (2.3) and the identity (ref. [4], p. 5) sums over k , m and n in terms of zeta functions or ratios of zeta functions using Eq. (7.1) is trivially established by taking Mellin transforms and evaluating the

$$\begin{aligned} (7.1) \quad & \sum_{\infty}^{k=1} \sum_{\infty}^{m=1} \sum_{\infty}^{n=1} \mu(m) \exp(-km_n x) \\ &= \sum_{\infty}^{k=1} \sum_{\infty}^{m=1} |\mu(m)| \exp(-mk_x) \end{aligned}$$

A variety of interesting results involving sums over the Möbius function can be derived from Mellin transform methods. We illustrate this first with the assertion that

7. Assorted series and products

$$(6.20) \quad f(e^{-x}) = \sum_{\infty}^{m=1} \sigma^{-1}(m) e^{-mx}.$$

and a term-by-term integration gives

$$(6.19) \quad f(e^{-x}) = \frac{1}{2\pi i} \int_{c+\infty}^{c-i\infty} x^{-s} F(s) \sum_{\infty}^{m=1} \frac{m}{\sigma^{-1}(m)} ds \quad (c = \operatorname{Re}(s) > 1)$$

where $\sigma^a(m)$ is the sum of the a th powers of the divisors of m . Eq. (6.4) thus becomes

$$(6.18) \quad \zeta(s) \zeta(s-a) = \sum_{\infty}^{m=1} \frac{m}{\sigma^a(m)},$$

$$T_{\pm}(x, z) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{|\mu(m)|}{n} (\mp)^{n-1} z^n \exp(-mnx). \quad (7.4)$$

We shall not address in detail the justification for the interchange of orders of summations in double sums, or for the interchange of orders of summation and integration. Adequate convergence to permit this is either clear, or secured by restricting $\operatorname{Re}(s)$ to sufficiently large values.

Taking the Mellin transform over x , we have

$$\int_0^{\infty} x^{s-1} T_{\pm}(x, z) dx = F(s) \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{|\mu(m)|}{m^n n^{s+1}} (\mp)^{n-1} z^n. \quad (7.5)$$

Using eq. (7.2), we find that

$$\int_0^{\infty} x^{s-1} T_{\pm}(x, z) dx = \frac{F(s) \zeta(s)}{\zeta(2s)} \sum_{n=1}^{\infty} \frac{(\mp)^{n-1} z^n}{n^{s+1}}. \quad (7.6)$$

Expanding $1/\zeta(2s)$ as $\sum_{m=1}^{\infty} \mu(m) m^{-2s}$, we find that

$$\int_0^{\infty} x^{s-1} T_{\pm}(x, z) dx = F(s) \zeta(s) \sum_{m=1}^{\infty} \mu(m) \sum_{n=1}^{\infty} \frac{(\mp)^{n-1} z^n}{m^{2s} n^{s+1}}. \quad (7.7)$$

Recognizing $m^{-2s} n^{-s} F(s) \zeta(s)$ as the Mellin transform of $\sum_{k=1}^{\infty} \exp(-m^2 n k x)$, we may now write

$$\begin{aligned} \int_0^{\infty} x^{s-1} T_{\pm}(x, z) dx &= \int_0^{\infty} x^{s-1} \sum_{k=1}^{\infty} \sum_{m=1}^{\infty} \mu(m) \sum_{n=1}^{\infty} \frac{(\mp)^{n-1} z^n}{m^{2s} n^{s+1}} \\ &\quad \times [\exp(-m^2 k x)]^n dx, \end{aligned} \quad (7.8)$$

and the sum over n can now be expressed as a logarithm. Inverting the Mellin transforms, we deduce that

$$T_{\pm}(x, z) = \pm \sum_{k=1}^{\infty} \sum_{m=1}^{\infty} \mu(m) \log[1 \pm z \exp(-m^2 k x)]. \quad (7.9)$$

Recalling eq. (7.3) and exponentiating, we obtain

$$\prod_{m=1}^{\infty} [1 \pm |\mu(m)| z \exp(-mx)]^{\mp 1} = \prod_{k=1}^{\infty} \prod_{m=1}^{\infty} [1 \pm z \exp(-m^2 k x)]^{\pm \mu(m)}. \quad (7.10)$$

Expanding the denominators using $\zeta(s) = \sum_{n=1}^{\infty} u(n) n^{-s}$, we obtain

$$(7.16) \quad \frac{1}{\zeta(s)} \sum_{n=1}^{\infty} z^{2n+1} = \frac{\zeta(s)}{F(s)} \sum_{n=0}^{\infty} z^{2n+1} \pm \frac{\zeta(2s)}{F(s)\zeta(s)} \sum_{n=1}^{\infty} z^{2n} \int_x^0 x^{s-1} U^{\pm}(x, z) dx$$

Taking Mellin transforms of both sides and evaluating the sums over m using eqs. (2.3) and (7.2), we deduce that

$$(7.15) \quad \begin{aligned} & \pm \sum_{n=1}^{\infty} \frac{n}{|u(m)|} z^n \exp(-mx) \\ & \text{and odd} \\ & U^{\pm}(x, z) = \sum_{n=1}^{\infty} \frac{n}{|u(m)|} z^n \exp(-mx) \end{aligned}$$

we have

$$\left. \begin{aligned} & u(m), & n \text{ even}, \\ & |u(m)|, & n \text{ odd}, \end{aligned} \right\} = \begin{cases} |u(m)|, & n \text{ even}, \\ u(m), & n \text{ odd}, \end{cases}$$

Expanding the logarithm and noting that

$$(7.14) \quad U^{\pm}(x, z) = \pm \sum_{n=1}^{\infty} \log[1 \mp u(m) z \exp(-mx)].$$

For a slightly harder example, consider

$$(7.13) \quad T^{\pm}(x, 1) = \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} u(m) \alpha^{-1}(n) \exp(-m^2 nx).$$

Using eq. (6.20), we may deduce that (the last equality follows from eq. (6.3)). Inverting the Mellin transform and

$$(7.12) \quad x^{s-1} \int_x^0 u(m) f(\exp(-mx)) dx =$$

$$(7.11) \quad \int_x^0 x^{s-1} T^{\pm}(x, 1) dx = F(s) \zeta(s) \zeta(s+1) \sum_{n=1}^{\infty} u(m) m^{-2s}$$

In the special case $z = 1$, selecting the formula for $T^{\pm}(x, z)$, eq. (7.7) reduces to

$$\begin{aligned} & \int_0^{\infty} x^{s-1} U_{\pm}(x, z) dx \\ &= \Gamma(s) \sum_{m=1}^{\infty} \mu(m) \sum_{n=0}^{\infty} \frac{z^{2n+1}}{m^s (2n+1)^{s+1}} \\ &\mp \Gamma(s) \zeta(s) \sum_{m=1}^{\infty} \mu(m) \sum_{n=1}^{\infty} \frac{z^{2n}}{m^{2s} (2n)^{s+1}} \end{aligned} \quad (7.17)$$

$$\begin{aligned} &= \int_0^{\infty} x^{s-1} \sum_{m=1}^{\infty} \mu(m) \sum_{n=0}^{\infty} \frac{z^{2n+1}}{2n+1} \exp[-(2n+1)mx] dx \\ &\mp \int_0^{\infty} x^{s-1} \zeta(s) \sum_{m=1}^{\infty} \mu(m) \sum_{n=1}^{\infty} \frac{z^{2n}}{2n} \exp[-2m^2 nx] dx, \end{aligned} \quad (7.18)$$

where in passing from eq. (7.17) to eq. (7.18), we have replaced $\Gamma(s) m^{-s} (2n+1)^{-s}$ and $\Gamma(s) m^{-2s} n^{-s}$ respectively by the Mellin transforms of $\exp[-(2n+1)mx]$ and $\exp[-2m^2 nx]$. The sums over n can now be evaluated in terms of logarithms, and if $\zeta(s)$ is expanded in its Dirichlet series, we can express the entire right-hand side as a Mellin transform. Inverting this transform, we obtain

$$\begin{aligned} U_{\pm}(x, z) &= \frac{1}{2} \sum_{m=1}^{\infty} \mu(m) \log\left(\frac{1+z \exp(-mx)}{1-z \exp(-mx)}\right) \\ &\pm \frac{1}{2} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \mu(m) \log[1-z^2 \exp(-2m^2 nx)]. \end{aligned} \quad (7.19)$$

If we return to eqs. (7.3) and (7.6), we have (setting $z = 1$ and selecting the formula for $T(x, z)$)

$$\int_0^{\infty} x^{s-1} \sum_{n=1}^{\infty} \log\{|1 - |\mu(n)| \exp(-nx)\|^{-1}\} dx = \frac{\Gamma(s) \zeta(s) \zeta(s+1)}{\zeta(2s)}. \quad (7.20)$$

If we multiply both sides of this equation by m^{-2s} and sum over m , we obtain

$$\int_0^{\infty} x^{s-1} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \log\{|1 - |\mu(n)| \exp(-m^2 nx)\|^{-1}\} dx = \Gamma(s) \zeta(s) \zeta(s+1). \quad (7.21)$$

Recognizing the right-hand side in terms of the Mellin transform of Euler's

which is equivalent to the following identity for infinite products:

$$\sum_{m=1}^{M-1} \log[1 \pm u(m)] z \exp(-m\pi x) = \sum_{k=1}^K \log[1 \pm z \exp(-kx)], \quad (7.26)$$

If we make $m_n x$ the new integration variable on the right-hand side, the sum over n may be identified as $\zeta(2s)$, while the sum over m is $1/\zeta(2s)$. Inverting the Mellin transform, we deduce that

$$\ln(m) \log[1 + z \exp(-m_n z kx)] dx. \quad (7.25)$$

$$x \cdot p \left[(x_{\zeta} \cdot u \cdot m -) \cdot d x \otimes z \mid (u) \cdot n' \right] \mp 1] \otimes \text{obj} \sum_{\infty}^{\infty} \sum_{\infty}^{\infty} \sum_{1-s}^{1-m} x^s \int_0^0$$

These are other interesting generalizations of these ideas, which take us into the theory of theta functions, some key results of which are collected in the appendix. If we replace x by n^2x in eq. (7.9), sum over n and take the Mellin transform, we obtain

We have removed the factor of $|u(n)|$ from the denominator of the left-hand side by noting that the summand is nonzero only when $|u(n)| = 1$.

$$\cdot \sum_{\alpha}^m z^{\alpha} D^{\alpha}(u) = \frac{1}{\prod_{\alpha} m_{\alpha}!} \sum_{\alpha} \sum_{\beta}^m \frac{z^{\alpha}}{m_{\alpha}!} |u|^{m_{\alpha}} u^{\alpha} \quad (7.24)$$

The right-hand side is a Lambert series. Using Eq. (3.20) we may express it as a power series. In this case, we determine b_s , by the requirement that $\sum_{n=1}^{\infty} b_n = \zeta(s-1)$. From Eq. (7.18), we see that $b_s = a(s-1)$, the sum of the divisors of s , and we arrive at the far from self-evident result that

$$\cdot \sum_{\infty}^{\frac{1}{m}} \sum_{\infty}^{(n) \pi} = \frac{(n) \pi}{m} \sum_{\infty}^{\frac{1}{m}} \sum_{\infty}^{(n) \pi} \quad (7.23)$$

If we now write $z = \exp(-x)$ and differentiate with respect to x , we obtain the identity

$$(7.22) \quad \sum_{m=1}^m \log([1 - \pi_m(n)] \exp(-m\chi)) = \{ \}_{-1} \{ [(x_m u_m - \exp(-m\chi))]_{-1} \}.$$

product (via eq. (6.2)), we have

$$\prod_{m=1}^{\infty} \prod_{n=1}^{\infty} [1 \pm |\mu(m)| z \exp(-mn^2 x)] = \prod_{k=1}^{\infty} [1 \pm z \exp(-kx)]. \quad (7.27)$$

In the appendix, we summarize some key results from the theory of theta functions, one of which is the infinite product representation

$$\vartheta_3(z, q) = Q \prod_{n=1}^{\infty} [1 + 2q^{2n-1} \cos(2z) + q^{4n-2}], \quad (7.28)$$

where

$$Q = \prod_{n=1}^{\infty} (1 - q^{2n}). \quad (7.29)$$

Using eq. (7.27) we can rewrite the last equation as

$$Q = \prod_{m=1}^{\infty} \prod_{n=1}^{\infty} [1 - |\mu(m)| q^{2mn^2}]. \quad (7.30)$$

The multiplicand in the product (7.28) can be factored as $(1 + q^{2n-1} e^{2iz})(1 + q^{2n-1} e^{-2iz})$. In each product, we may now use the identity (7.27) with appropriate identifications of z and e^{-x} , giving

$$\vartheta_3(z, q) = Q \prod_{m=1}^{\infty} \prod_{n=1}^{\infty} (1 + |\mu(m)| q^{2mn^2-1} e^{2iz})(1 + |\mu(m)| q^{2mn^2-1} e^{-2iz}). \quad (7.31)$$

In a similar manner,

$$\vartheta_4(z, q) = Q \prod_{m=1}^{\infty} \prod_{n=1}^{\infty} (1 - |\mu(m)| q^{2mn^2-1} e^{2iz})(1 - |\mu(m)| q^{2mn^2-1} e^{-2iz}). \quad (7.32)$$

Similar product representations exists for $\vartheta_1(z, q)$ and $\vartheta_2(z, q)$, so that in particular

$$\begin{aligned} \prod_{n=1}^{\infty} [1 - 2q^{2n} \cos(2z) + q^{4n}] &= \prod_{m=1}^{\infty} \prod_{n=1}^{\infty} [1 - 2|\mu(m)| q^{2mn^2} \cos(2z) \\ &\quad + |\mu(m)| q^{4mn^2}]. \end{aligned} \quad (7.33)$$

Differentiation of the logarithm of eq. (7.33) with respect to z gives, on cancellation of a factor of $4 \sin(2z)$ common to both sides,

$$\sum_{n=1}^{\infty} \operatorname{sech}_z^2(n\pi) = \frac{1}{4} K(2^{-1/2}) E(2^{-1/2}) = \frac{1}{\pi} + \frac{8\pi^2}{F_4(\tfrac{1}{4})}. \quad (7.39)$$

where $K(k)$ the complete elliptic integral of the first kind, $K(k) = K(\sqrt{1-k^2})$ and $\theta = \pi K(k)/K(k)$. For $f=2$, the series can be summed for $\theta = \pi$ using the identity [49]

$$\sum_{n=1}^{\infty} |\mu(m)| \sum_{m=1}^{\infty} \frac{q^{2mn^2}}{1+q^{4mn^2}} = \frac{1}{2} \sum_{m=1}^{\infty} |\mu(m)| \sum_{n=1}^{\infty} \operatorname{sech}(mn^2\theta) = \frac{K(k)}{2\pi} - \frac{1}{\pi}, \quad (7.38)$$

so that

For $f=1$, the series on the left-hand side is a special case of a series for the elliptic function dn given by Whittaker and Watson [30] (p. 511, example 1).

$$\sum_{n=1}^{\infty} \left(\frac{\cosh(n\theta)}{1+q^{4n^2}} \right)^f = \sum_{m=1}^{\infty} |\mu(m)| \sum_{n=1}^{\infty} \left(\frac{\cosh(mn^2\theta)}{1+q^{4mn^2}} \right)^f, \quad f=1, 2, 3, \dots \quad (7.37)$$

If we now set $q = e^{-z}$, we obtain

$$\sum_{n=1}^{\infty} \left(\frac{1+q^{4n}}{1+q^{2n}} \right)^f = \sum_{m=1}^{\infty} |\mu(m)| q^{2mn^2} \sum_{n=1}^{\infty} \left(\frac{1+q^{4mn^2}}{1+q^{2mn^2}} \right)^f = \sum_{m=1}^{\infty} |\mu(m)| q^{2mn^2} \left(\frac{1+q^{4m}}{1+q^{2m}} \right)^f, \quad f=1, 2, 3, \dots \quad (7.36)$$

Since $|\mu(m)|$ takes only the values 0 and 1, this result may be simplified to

$$\sum_{n=1}^{\infty} \left(\frac{1+q^{2n}}{1+q^n} \right)^f = \sum_{m=1}^{\infty} \left(\frac{1+q^{4m}}{1+q^{2m}} \right)^f = \sum_{m=1}^{\infty} \left(\frac{1+q^{4m}}{1+q^{2m}} \right)^f, \quad f=1, 2, 3, \dots \quad (7.35)$$

The summand in both sides can be written as $a[1 - 2a \cos(2z)]^{-1}$, with $a = q^{2n}/(1+q^{2n})$ and $a = |\mu(m)|q^{2mn^2}/(1+|\mu(m)|q^{4mn^2})$ respectively, and expanded in powers of $\cos(2z)$. Equating the coefficients of equal powers of $\cos(2z)$, we obtain

$$\begin{aligned} & \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{1-2|\mu(m)|q^{2mn^2}\cos(2z)+|\mu(m)|q^{4mn^2}}{|\mu(m)|q^{2mn^2}} \\ &= \sum_{n=1}^{\infty} \frac{1-2q^{2n}\cos(2z)+q^{4n}}{q^{2n}}. \end{aligned} \quad (7.34)$$

8. Ewald sums and quasi-crystals

We conclude our discussion of tautologies by noting some consequences of the identity

$$\sum_{m=1}^{\infty} |\mu(m)| Q(mx) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \mu(m) Q(m^2 nx). \quad (8.1)$$

This identity is easily established by taking Mellin transforms with respect to x and evaluating the series in terms of zeta functions. In the special case $Q(x) = \exp(-\epsilon x^2) \cos(x)$, we obtain

$$\begin{aligned} \sum_{m=1}^{\infty} |\mu(m)| \exp(-m^2 \epsilon x^2) \cos(mx) &= \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \mu(m) \exp(-m^4 n^2 \epsilon x^2) \\ &\quad \times \cos(m^2 nx). \end{aligned} \quad (8.2)$$

If we take $\epsilon = 0$, we have, formally,

$$\sum_{m=1}^{\infty} |\mu(m)| \cos(mx) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \mu(m) \cos(m^2 nx). \quad (8.3)$$

The series do not converge, but may be interpreted in the sense of generalized functions [31]. From eq. (3.24), we have

$$\sum_{n=-\infty}^{\infty} \delta(y - n) = \sum_{n=-\infty}^{\infty} \cos(2\pi ny), \quad (8.4)$$

and setting $2\pi y = m^2 x$, we have

$$\begin{aligned} \sum_{n=1}^{\infty} \cos(m^2 nx) &= \frac{1}{2} \sum_{n=-\infty}^{\infty} \delta\left(\frac{m^2 x}{2\pi} - n\right) - \frac{1}{2} \\ &= \frac{1}{2} \left[\sum_{n=-\infty}^{\infty} \frac{2\pi}{m^2} \delta\left(x - \frac{2\pi n}{m^2}\right) - 1 \right]. \end{aligned} \quad (8.5)$$

Hence

$$\sum_{m=1}^{\infty} |\mu(m)| \cos(mx) = \frac{1}{2} \sum_{m=1}^{\infty} \mu(m) \left[\sum_{n=-\infty}^{\infty} \frac{2\pi}{m^2} \delta\left(x - \frac{2\pi n}{m^2}\right) - 1 \right]. \quad (8.6)$$

This formula relates a sum of cosines, the Fourier transform of a set of delta functions at selected points where the Möbius function is non-zero, to a double sum of delta functions. This is precisely the kind of relation that is needed for a description of quasi-crystalline or other pseudo-ordered structures [50].

surfaces. For example, the zero potential surface of the CsCl lattice has the zero potential surfaces for all known crystals have the symmetry of minimal which is the product of periodic delta functions for the NaCl lattice.

(8.10)

$$p(x, y, z) = \frac{2}{\pi} \sum_{n=-\infty}^{\infty} \sum_{m=-\infty}^{\infty} (-1)^{l+m+n} g(x - l) g(y - m) g(z - n),$$

obtain the potential corresponding to the charge density, obtaining $l = m = n = 2$ and $a = \pi$ in eq. (8.9) and using eq. (A.21). For example, and a formula for the Fourier transform of the potential [53, 54]. For solutions and a potential for all standard lattices, and easily construct numerical write down a potential of two integrals of the form (8.8), we can of the form (8.8), or in the difference of two integrals in integrals value 1. By choosing an appropriate combination of theta functions in the second argument is zero, g_1 and g_3 vanish, while g_2 and g_4 , take the When their second argument is zero, g_1 and g_3 vanish, while g_2 and g_4 , take the theta functions reduce to infinite series of periodically spaced delta functions. As discussed in the appendix, when their second argument is unity, all four

(8.9)

$$\Delta^2 V = 2a^2 [\vartheta'_1(ax, e^{-\frac{z}{a}}) \vartheta_m(ay, e^{-\frac{y}{a}}) \vartheta''_n(az, e^{-\frac{z}{a}})]_x^0,$$

derivative of $\vartheta'_1(ax, e^{-\frac{z}{a}}) \vartheta_m(ay, e^{-\frac{y}{a}}) \vartheta''_n(az, e^{-\frac{z}{a}})$ and it follows that equation (A.6), we find that the integrated becomes a multiple of the Δ^2 to eq. (8.8), take it under the integral and use the partial differential the same partial differential equation (A.6). If we apply the Laplace operator properties collected in the appendix, the theta functions satisfy where the theta functions $\vartheta_i(z, y)$ ($i = 1, 2, 3, 4$) are defined and their relevant

(8.8)

$$V(x, y, z) = \int_x^0 \vartheta'_1(ax, e^{-\frac{z}{a}}) \vartheta_m(ay, e^{-\frac{y}{a}}) \vartheta''_n(az, e^{-\frac{z}{a}}) r dr,$$

where p is a periodic sum of products of delta functions with appropriate symmetry. Consider the potential defined by

(8.7)

$$\Delta^2 V = -4\pi p,$$

that the potential V has to satisfy Poisson's equation that the potential V has to satisfy Poisson's equation. The general problem can more easily be treated if we note array of charges. The problem is to find the electrostatic potential set up by an Nimbam [55]. The problem is to find the electrostatic potential set up by an inorganic chemistry, further explored by Barnes [53], Barnes et al. [54] and Scheniring and Nesper [51] and Andersson et al. [52] on minimal surfaces in

topology of the Schwarz P minimal surface [56]. The electrostatic potential is also needed in the derivation of the zero point energy of the system and in crystallographic analysis. From eqs. (8.2) and (8.3) we can construct a whole series of new pseudolattices from the "Möbius theta function"

$$\Theta(z, q) = \sum_{m=1}^{\infty} |\mu(m)| q^{m^2} \cos(2mz) \quad (8.11)$$

and related series. Such lattices may also satisfy charge neutrality, since over long- n -intervals, the number of positive $\mu(n)$ and the number of negative $\mu(n)$ encountered are closely balanced^{*4}. Because of the relation of these pseudolattices to ordinary close-packed Bravais lattices revealed through the infinite products of section 7, we can expect to find a rich field of applications through such considerations.

That part of classical analysis which celebrates the properties of individual higher transcendental functions has fallen out of favour in recent years, as it has become more fashionable to speak of the general in mathematics, rather than the particular. For this reason, Ramanujan, this century's greatest master of the particular, has not always been ranked as highly as he deserves. Even G.H. Hardy has remarked that his work would be greater if it were less strange. The Greek poet Archilochus wrote "The fox knows many things, but the hedgehog knows one big thing". Several authors, most notably Sir Isaiah Berlin in an essay on Tolstoy [59], have taken this cryptic statement as the contrasting of two different styles of thinkers, those who "relate everything to a single central vision" (hedgehogs) and those who "pursue many ends, often unrelated and even contradictory" (foxes). It is tempting to classify Ramanujan as a fox.

In this paper, we have pursued a number of mathematical tautologies. As a consequence of the evolution of accepted mathematical notation, many of the equations appear at first glance to have little in common. However, using the Mellin transform and the Riemann zeta function as our Rosetta stone, the simplicity and naturalness of the interrelations becomes apparent. We offer our analysis as modest support to the conjecture that Ramanujan may have been a hedgehog after all.

^{*4} Whether they balance exactly in the limit of an infinitely long interval is a delicate question. Let $M(N) = \sum_{n=1}^N \mu(n)$. The assertion that $M(N) = O(N^{1/2+\epsilon})$ for all $\epsilon > 0$ is precisely equivalent (ref. [4], p. 315) to the Riemann hypothesis that all complex zeros of $\zeta(s)$ lie on the line $\text{Re}(s) = \frac{1}{2}$. Edwards [57] (p. 6) has described the proof or refutation of the Riemann hypothesis as "unquestionably the most celebrated problem in mathematics". If the nonzero values of $\mu(n)$ were a sequence of independent random variables, taking the values 0 and 1 with equal probability, then by the law of the iterated logarithm (ref. [58], p. 205), we would have $\limsup_{N \rightarrow \infty} M(N)/\sqrt{N \log \log N} = \text{constant}$.

$$\vartheta_4(z, b) = G \prod_{n=1}^{\infty} [1 + 2b^{2n-1} \cos(2z) + b^{4n-2}], \quad (\text{A.6})$$

$$\vartheta_2(z, b) = 2G b^{1/4} \cos z \prod_{n=1}^{\infty} [1 + 2b^{2n} \cos(2z) + b^{4n}], \quad (\text{A.7})$$

$$\vartheta_3(z, b) = 2G b^{1/4} \sin z \prod_{n=1}^{\infty} [1 - 2b^{2n} \cos(2z) + b^{4n}], \quad (\text{A.8})$$

and have infinite product representations,

$$\frac{i\pi}{4} \frac{\partial^2 \vartheta}{\partial z^2} + \frac{\partial \vartheta}{\partial z} = 0 \quad (\text{A.9})$$

All four theta functions are solutions of the partial differential equation

$$\vartheta_4(z, b) = \vartheta_4(z | \tau). \quad (\text{A.5})$$

To indicate the dependence of the theta functions on τ , we define it is assumed here that $|q| < 1$, and we write $q = e^{i\pi\tau}$, with $\text{Im}(\tau) > 0$. To

$$\vartheta_4(z, b) = 1 + 2 \sum_{n=1}^{\infty} (-1)^n q^{n^2} \cos(2nz). \quad (\text{A.6})$$

$$\vartheta_3(z, b) = 1 + 2 \sum_{n=1}^{\infty} q^{n^2} \cos(2nz), \quad (\text{A.7})$$

$$\vartheta_2(z, b) = 2 \sum_{n=0}^{\infty} q^{(n+1/2)^2} \cos[(2n+1)z], \quad (\text{A.8})$$

$$\vartheta_1(z, b) = 2 \sum_{n=0}^{\infty} (-1)^n q^{(n+1/2)^2} \sin[(2n+1)z], \quad (\text{A.9})$$

The theta functions [21, 30] are defined by the series

Appendix

$$\vartheta_4(z, q) = G \prod_{n=1}^{\infty} [1 - 2q^{2n-1} \cos(2z) + q^{4n-2}], \quad (\text{A.10})$$

where

$$G = \prod_{n=1}^{\infty} (1 - q^{2n}). \quad (\text{A.11})$$

The theta functions are intimately related to the elliptic functions and elliptic integrals, and in view of the preceding infinite product representations, are also relevant to problems in the theory of partitions. (In the notation of section 6, $G = F_E(q^2)$.) The many interrelations between the theta functions and the plethora of transformation formulæ have given the topic something of a mystique. However, these apparent subtleties are neither more nor less deep than the tautologies pursued in the present paper. A case in point is the theta function transformation ("Jacobi's imaginary transformation")

$$\vartheta_3(z|\tau) = (-i\tau)^{-1/2} \exp\left(\frac{z^2}{i\pi\tau}\right) \vartheta_3(z/\tau| -1/\tau). \quad (\text{A.12})$$

This formula is equivalent to the assertion that

$$\sum_{m=-\infty}^{\infty} \exp(m^2 i\pi\tau + 2miz) = (-i\tau)^{-1/2} \sum_{m=-\infty}^{\infty} \exp[(z - m\pi)^2/i\pi\tau], \quad (\text{A.13})$$

a special case of which is eq. (3.22). If we write $z = \pi x$ and $\tau = i\varepsilon$, where $\varepsilon > 0$, eq. (A.13) becomes

$$\sum_{m=-\infty}^{\infty} \exp(-m^2 \pi\varepsilon + 2\pi mix) = \varepsilon^{-1/2} \sum_{m=-\infty}^{\infty} \exp[-(\pi/\varepsilon)(x - m)^2]. \quad (\text{A.14})$$

It is easily verified that in the limit $\varepsilon \rightarrow 0$,

$$\varepsilon^{-1/2} \exp[-(\pi/\varepsilon)(x - m)^2] \rightarrow \delta(x - n\pi), \quad (\text{A.15})$$

so that the generalized function identity

$$\sum_{m=-\infty}^{\infty} \delta(x - m) = \sum_{m=-\infty}^{\infty} \exp(2\pi mx i) \quad (\text{A.16})$$

is a special limiting case of the theta-function transformation (A.12). Although it is more usual to derive the theta function transformation (A.12) from eq. (A.16) (cf. ref. [31], p. 70), implicitly regarding the general function identity as the more fundamental formula, we would be equally justified in taking the theta function identity as fundamental.

$$= \sum_{x=-\infty}^{\infty} [2g(x-2m) - g(x-m)] = \sum_{x=-\infty}^{m=-\infty} (-1)_m g(x-m). \quad (\text{A.21})$$

$$g_3^z(\pi x, 1) = g_3^z(\frac{z}{\pi} \pi x, 1) - g_3^z(\pi x, 1) = \sum_{x=-\infty}^{m=-\infty} [g(\frac{z}{\pi} x - m) - g(x - m)] \quad (\text{A.20})$$

In particular, we have

$$g_3^z(z, y) = g_3^z(2z, y) + g_3^z(2z, -y). \quad (\text{A.19})$$

and

$$g_4^z(z, y) = -g_2^z(z + \frac{z}{\pi}, y), \quad g_4^z(z, y) = g_3^z(z + \frac{z}{\pi}, y) \quad (\text{A.18})$$

the series being interpreted in the sense of the theory of generalized functions [31]. Expressions for $g_3^z(z|0) = g_3^z(z, 1)$ via the identities (ref. [30], p. 464) = $g_4^z(z, 1)$ can be deduced from eq. (A.17) via the identities (ref. [30], p. 464) = $g_4^z(z, 1)$. Having obtained eq. (A.16), we may now assign meanings to the theta

$$g_3^z(z|0) = g_3^z(z, 1) = 1 + 2 \sum_{x=-\infty}^{n=1} \cos(2xz) = \sum_{x=-\infty}^{m=-\infty} \exp(2miz) = \sum_{x=-\infty}^{m=-\infty} g(z/\pi - m) \quad (\text{A.17})$$

functions for $\tau = 0$, for example,
